MIRRORS MEASURE HOT STEEL PLATE

Steel plates must be accurate to within one-half inch in width before they are rolled into long sheets. At present these plates are measured with a hand gage as they move along plates up to thirteen feet in width. A system of mirrors which enable workmen to measure at a glance the width of the yellow hot steel slabs has been devised.

A mirror is aimed at the steel as it leaves the rolls of the mill. A second mirror is aimed at a chart with widths on it. Images from both mirrors are aimed at a third mirror. From these two superimposed images the rolling mill operator can read the width of the steel plate at a glance.
